

Configure *monerod* as an I2P Hidden Service

07 November 2018

author: prefers to remain anonymous

Introduction

This paper will describe how to configure the Monero daemon (*monerod*) as an I2P hidden service. The value-added here is to provide an access path from Monero wallets to a remote Monero full node while hiding the Monero wallet machine's IP address. Hiding the Monero wallet client's IP address helps to maintain anonymity of Monero transactions at the network layer.

Since *monerod* needs to connect to the global Monero network to maintain an up-to-date blockchain along with the ability to process transactions, there are risks of exposing the IP address of the machine running the *monerod* service to prying eyes. There are a multitude of approaches to mitigating this risk which will be discussed in subsequent papers which will include the use of VPNs, Tor, and eventually the Kovri project which will integrate Monero with the I2P network.

Even though the machine running the I2P *monerod* hidden service incurs the risk of IP address exposure, this risk does not fall on the clients (wallets) that use the hidden service. Providing access to the I2P *monerod* hidden service to multiple clients provides plausible deniability to users of the hidden service.

The diagram below illustrates the domain space for this paper.

The I2P monerod hidden service communicates with client wallets through I2P tunnels. The tunnel endpoints are cryptographic constructs called *tunnel destinations* (not IP address:port number). All data transported via I2P tunnels are encrypted end-to-end. For additional information regarding the I2P protocol see: <https://geti2p.net/en/docs/how/intro>

The remainder of this paper will describe:

- Installing and running monerod on the “hidden service” computer
- Installing and running the I2P router on the “hidden service” computer
- Configuring the I2P monerod hidden service
- Configuring I2P client tunnels to use the I2P monerod hidden service
- Connecting wallet(s) to the I2P monerod hidden service

All of the computers used to provide the I2P monerod hidden service described in this paper were running a 64-bit Linux operating system.

Installing and Running *monerod* on Hidden Service Computer

First you need to download the latest Monero software package. Goto <https://getmonero.org/downloads/>

and download the proper package for your computer. Since we are using a 64-bit Linux computer for our hidden service machine, we are going to download the **Linux 64-bit Command-Line Tools Only** software package as shown in the image below.

 Linux, 64-bit	
Linux, 64-bit	Linux, 64-bit Command-Line Tools Only
Current Version: 0.13.0.3 Beryllium Bullet	Current Version: 0.13.0.2 Beryllium Bullet
SHA256 Hash (GUI):	SHA256 Hash (CLI):
b26fe2fb921c5ab7f774ceac69cc0ff5ee0e0d730dd902aa4 f45046320e58749	a59fc0fffb325b4f92a5b500438bf340ddbf78e91581eb4df 95ad2d5e5fb42a8

Extract the downloaded file, then go to the directory in a terminal and type the following command:

```
./monerod
```

If everything was done successfully, the Monero daemon will be running and displaying output on your terminal screen. Please consult <https://getmonero.org/> for specific information regarding the proper installation of the Monero software.

Installing and Running I2P Router on Hidden Service Computer

You must have a Java runtime environment on your computer to run the I2P router. I used the **openjdk-8-jre-headless** package. To install on Linux (Debian/Ubuntu) I ran the following commands:

```
sudo apt-get update
```

```
sudo apt-get install openjdk-8-jre-headless
```

When the java runtime environment is installed, download and install the I2P router from:

<https://geti2p.net/en/download>

Follow the installation instructions on the I2P download page.

i2pinstall_0.9.37.jar

Mirror:  sigterm.no

[select alternate mirror](#)

[sig](#)

Download that file and double-click it (if that works) or type `java -jar i2pinstall_0.9.37.jar` in a terminal to run the installer. On some platforms you may be able to right-click and select "Open with Java".

Command line (headless) install:

Download the graphical installer file above and run `java -jar i2pinstall_0.9.37.jar -console` from the command line.

After installation, start the I2P router by going to the directory where I2P is installed and enter:

```
./i2prouter start
```

Configuring the I2P monerod Hidden Service

Go to the I2P Hidden Services Manager (on your I2P router machine) at:

<http://127.0.0.1:7657/i2ptunnelmgr>

(The web page is served up by your local machine, not an external web site). You should see a page similar to the one shown below:

Target

Host: 127.0.0.1

Port: required

Use SSL to connect to target

Local destination

Private key file

ADVANCED NETWORKING OPTIONS

Tunnel Options

Length

Variance

Count

Backup Count

Enter in the form:

Name = monerod hidden service

Check the *Automatically start tunnel when router starts* checkbox

Port = 18081

The your screen should look like the one shown below:

The screenshot shows the I2P Hidden Services Manager interface. On the left is a sidebar with navigation links: ROUTER INFO, BANDWIDTH IN/OUT, Network: Firewallled, I2P SERVICES (Email, Torrents, Web Server, SecureMail), I2P INTERNALS (Addressbook, Graphs, Help, Hidden Services Manager, Logs, NetDB, Peers, Profiles, Tunnels), HELP & FAQ (Advanced Settings, Changelog, Configuration, FAQ, Legal, Reachability, Sidebar, Troubleshoot), and PEERS (Active: 23 / 246, Fast: 30, High Capacity: 53). The main area is titled 'HIDDEN SERVICES MANAGER' and contains a 'NEW SERVER SETTINGS' form. The form has fields for Name (monerod hidden service), Type (Standard server), Description, Auto Start Tunnel (checked), Target (Host: 127.0.0.1, Port: 18081, Use SSL to connect to target: unchecked), Local destination, and Private key file (i2ptunnel12-privKeys.dat). Below this is an 'ADVANCED NETWORKING OPTIONS' section with dropdowns for Tunnel Options (3 hop tunnel (high anonymity)), Variance (0 hop variance (no randomization, consistent performance)), Count (2 inbound, 2 outbound tunnels (standard bandwidth and reliability)), and Backup Count (0 backup tunnels (0 redundancy, no added resource usage)).

Optional:

If you want to require users to possess an encryption key to use the I2P monerod hidden service, you can encrypt the *leaseset* and generate the key. This will only allow clients with the encryption key to connect to the I2P monerod hidden service. To encrypt the leaseset and generate the encryption key, scroll down the page to the section labeled **Encrypt Leaseset**. Check the *Only allow clients with the encryption key to connect to this server* checkbox and then click the *Generate* button. The screen should resemble the one presented below.

The screenshot shows the 'Encrypt Leaseset' section. It has a checkbox labeled 'Only allow clients with the encryption key to connect to this server' which is checked. Below this is an 'Encryption Key' field containing the text 'QG5QF1eLfp8bSP-QILk3fwPJQLIFHmZs~1aEKMxFIA=' and a 'Generate' button. To the right of the field is a link that says 'Generate New Key (Tunnel must be stopped first)'.

Users of the I2P monerod hidden service will then need to add the service *destination* and the *encryption key* in their I2P Keyring on their client tunnel machine (<http://127.0.0.1:7657/configkeyring>).

When finished, click the *Save* button at the bottom of the form. You should now see a new *monerod hidden service* similar to the one shown below.

I2P HIDDEN SERVICES					
Name	Type	Points at	Preview	Status	Control
 I2P webservice	HTTP server	127.0.0.1:7658	No Preview	  	<input type="button" value="Start"/>
Hostname: mysite.i2p Description: My eepsite					
 monerod hidden service	Standard server	127.0.0.1:18081	No Preview	  	<input type="button" value="Stop"/>
Destination: ldpnikuysadsz6tzowtbjub2eh12fu2hsgn3ks5djg5i22wzea.b32.i2p Description:					
New hidden service: <input type="text" value="HTTP"/> <input type="button" value="Create"/>					

Your tunnel *destination* will be different and you will need to reference this tunnel destination later when you setup your client tunnels. When the light in the hidden service *Status* field is green, your monerod hidden service will be operational and route requests to the I2P hidden service to the Monero daemon running on the machine.

Configuring I2P Client Tunnels

On a different (client) machine, repeat the following steps presented above:

- Install the Monero software package i.e., wallet (if not already installed)
- Install java runtime environment (if not already installed)
- Install I2P router (if not already installed)

On the client machine, go to the I2P Hidden Services Manager at:

<http://127.0.0.1:7657/i2ptunnelmgr>

(The web page is served up by your local machine, not an external web site). You should see a page similar to the one shown below:

HIDDEN SERVICES MANAGER

 **NEW PROXY SETTINGS**

Name	Type
New Tunnel1	Standard client

Description

Auto Start Tunnel

☐ Automatically start tunnel when router starts

Access Point

Port: required

Reachable by: 127.0.0.1 ▼

Use SSL?

☐ Clients use SSL to connect to tunnel

Tunnel Destination

required (name, name:port, or destination)

Shared Client

☐ Share tunnels with other clients and irc/httpclients? (Change requires restart of client proxy tunnel)

 **ADVANCED NETWORKING OPTIONS**

 Note: When this client proxy is configured to share tunnels, then these options are for all the shared proxy clients!

Give the tunnel a name.

Enter **18081** for the *Port* number (enter over the red “required” text).

Enter the *hidden service tunnel destination* (from the creation of the hidden service above) in the *Tunnel Destination* field (that has the red “required” text in it).

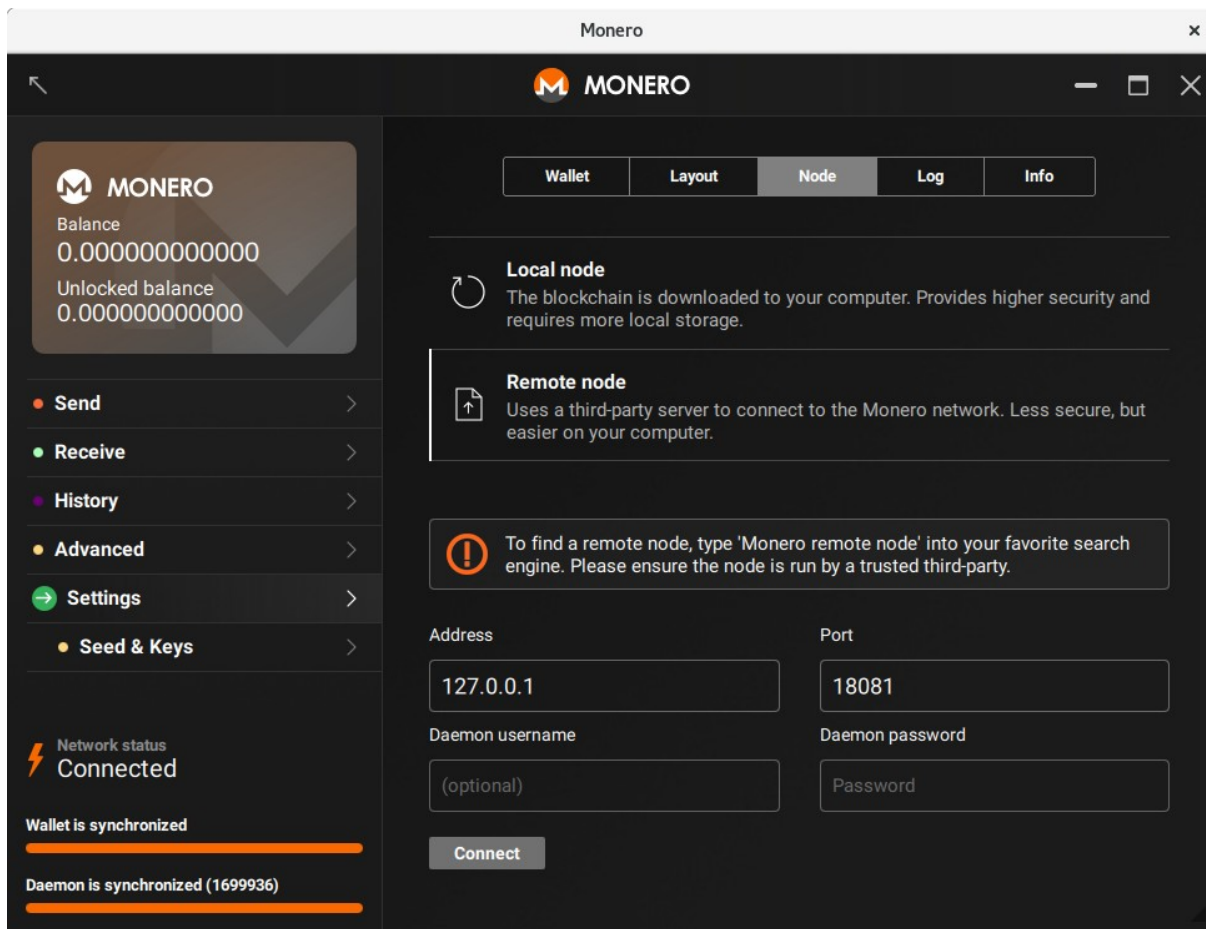

Then scroll to the bottom of the page and click the *Save* button.

You will need to start this tunnel prior to attempting to connect to the I2P monerod hidden service. When your done using the hidden service, you can stop the client tunnel.

Connecting Wallets to the I2P monerod Hidden Service

Now with the hidden service running on the hidden service machine and the client tunnel running on the client machine, you can connect your Monero wallet to the *I2P monerod hidden service*.

You can run the monero-wallet-cli on the client machine and it will access the Monero blockchain via the I2P monerod hidden service. You could also install the Monero GUI wallet client and it will access the I2P monerod hidden service as shown below.

Cycle times will be slower than running everything over the regular Internet because the I2P network is end-to-end encrypted and goes through multiple hops to reach destinations. However, remember that as a result, your wallet machine's IP address is no longer exposed to prying eyes and your network access to the Monero blockchain is anonymous.

Automating the I2P monerod hidden Service

To effectively operate an I2P monerod hidden service it is necessary to provide a level of service which attempts to keep both the monerod and i2prouter on the hidden service, machine up and running 24x7.

To do this on a Linux based operating system, *systemd* is utilized to automatically start monerd and the i2prouter when the computer boots up, and to restart monerod and i2prouter if either one terminates for any reason during operation.

To configure this level of service, two service files were written:

/etc/systemd/system/monerod.service:

```
[Unit]
Description=monerod.service
After network.target=monerod.service

[Service]
Type=forking
ExecStart=/home/user/monero-v0.13.0.4/monerod -detach -pidfile /tmp/monerod.pid
ExecStop=/home/user/monero-v0.13.0.4/monerod exit
PIDFile=/tmp/monerod.pid
User=user
Group=user
Restart=always
RestartSec=90

[Install]
WantedBy=multi-user.target
```

/etc/systemd/system/i2p.service:

```
[Unit]
Description=i2p.service
After network.target=i2p.service

[Service]
Type=forking
ExecStart=/home/user/i2p/i2prouter start
ExecStop=/home/user/i2p/i2prouter stop
ExecReload=/home/user/i2p/i2prouter restart
User=user
Group=user
Reload=always
Restart=always
RestartSec=90

[Install]
WantedBy=multi-user.target
```

*You can tweak the parameters in the two service files shown above as you see fit. Obviously the **User** and **Group** parameters will need to be modified for your machine. The path specifiers to **monerod** and the **i2prouter** will need to reflect the locations on your computer.*

Once the service files are placed into the `/etc/systemd/system` directory, you will need to issue the following commands:

```
sudo systemctl enable monerod.service    # enables the monerod services in systemd
sudo systemctl enable i2p.service        # enables the i2p.service in systemd
sudo systemctl daemon-reload             # reloads the systemd daemon
```

When the computer reboots, the monerod and i2p services should be automatically started.

You can issue the following commands to check the status of the services:

```
sudo systemctl status monerod.service
sudo systemctl status i2p.service
```

Read up on systemd to increase your knowledge.

When the services are up and running, you can open a terminal window and issue a *monerod exit* command to stop monerod. Then wait for systemd to restart it. Verify that the service is restarted and you should be good.

Similarly you can issue an *i2prouter stop* command. Then verify that the i2prouter has terminated. Then wait to verify that *systemd* has restarted the i2prouter. **As long as you configured the I2P monerod hidden service to - Automatically start tunnel when router starts** – your I2P monerod hidden service should be well positioned to attempt a 7x24 level of service.

VPN Option

I have installed an openvpn server on a VPS machine running Ubuntu 16.04.2 LTS. The version of openvpn installed is:

```
OpenVPN 2.3.10 x86_64-pc-linux-gnu [SSL (OpenSSL)] [LZO] [EPOLL] [PKCS11] [MH] [IPv6] built
on
Jun 22 2017
```

An .ovpn file generated from the openvpn server mentioned above was placed on my I2P monerod hidden service machine along with the openvpn client software to provide an operational VPN connection for the Monero daemon enabling the I2P monerod hidden service.

The hidden service machine was configured to prevent DNS leaks (checked with: <https://www.dnsleaktest.com/>).

The Monero daemon on the hidden service machine is started as:

```
cd monero-v0.13.0.4
./monerod -p2p-bind-ip 10.8.0.3
```

In my present setup, the Monero daemon doesn't support incoming connections on port 18080. I'm in the process of determining how to correct that. This lack of incoming connections still allows for the use of Monero, but it doesn't allow others to connect to the node to help synchronize their nodes.

Placing the I2P monerod hidden service machine behind a VPN provides an additional layer of plausible deniability in that the Monero daemon's access to the global Monero network now exposes the IP address of the VPN server rather than the IP address of the hidden services machine.

The risk exposure involves running a Monero full node that allows external client connectivity. All external client wallets that interact with the I2P monerod hidden service still do so anonymously through the I2P network.

If you wish to take this option, you will need to gain access to a VPN service that you can connect your hidden service machine to as a VPN client.

Conclusion

If you have any questions or would like assistance to get an I2P monerod hidden service established you can feel free to contact me via I2P-Bote.

Use I2P-Bote email destination:

iVCMAA149vIVByA0DfoTnboySJvfQl3d0nv~fmhkPH~qmlOl6VrNqMKYd3gpw4kLMDhWmc~aTs07z9UISd1fkO
